1. INTRODUCTION

1.1 DESCRIPTION

The TMS9914A provides an interface between a Microprocessor System and the General Purpose Interface Bus (GPIB) specified in the IEEE-488 1975/78 standards and the IEEE-488A 1980 supplement. The device is controlled and configured through 8-bit memory mapped registers and enables all aspects of the standards to be implemented, including talker, listener and controller.

1.2 KEY FEATURES

- Handles all IEEE-488 1975/78 functions
- Compatible with IEEE-488A 1980 supplement
- Talker and listener function (T,TE,L,LE)
- Automatic source and acceptor handshakes (SH,AH)
- Controller with pass control
- System Controller capabilities
- Device trigger and device clear capabilities (DT,DC)
- Optional automatically cleared 'request service bit'
- Parallel and serial poll facilities (PP)
- Remote/local function with local lockout (RL)
- Single or dual primary addressing
- Secondary address capabilities
- Direct interface to SN75160/161/162 bus transceivers with no additional logic
- Compatible with most microprocessors
- Direct memory access facilities
- Memory-mapped microprocessor interface

1.3 RELATIONSHIP TO THE TMS9914

The TMS9914A is compatible with the TMS9914 and may replace it in any application without software alterations. New features are included on the TMS9914A which increase the flexibility of the device. These features are disabled at power-up and must be programmed by the user as needed.

TMS9914A VS. TMS9914:

- 1) Byte Output interrupt modification (see Section 2.1.1 and Appendix B)
- 2) Reduced bus settling time T1 (see Section 2.1.6 and Section 3.3)
- 3) Modification to the Service Request Function (see Section 3.5)
- 4) Addition of a second request service (rsv) bit which is automatically cleared (see Section 2.1.6 and Section 3.5)

1.4 INTRODUCTION TO THE IEEE-488 1975/78 INTERFACE BUS

The GPIB is designed to allow up to 15 instruments within a localized area to communicate with each other over a common bus. Each device has a unique address, read from external switches at power-on, to which it responds. Information is transmitted in byte serial bit parallel format and may consist of either device-dependent data or interface messages, commonly referred to as data or commands, respectively.

Device data may be sent by any one device (the talker) and received by a number of other devices (listeners). Instructions, such as select range, select function, or measurement data for processing or printout, may be sent in this way.

One of the devices on the bus, designated the Controller in charge (Controller), may send interface control messages. Devices can be assigned to the bus as listeners or talkers by sending their unique talk or listen addresses and may be switched between remote and local control.

The bus itself consists of a 24-wire shielded cable. Eight lines carry data; 8 are control lines; 8 are signal and system grounds. A diagram showing the IEEE bus configuration is given in Appendix-A.

Three of the management lines operate as a three-line handshake between talker (or controller) and listeners. No new data is sent until each device addressed to listen has received the last byte and is ready for the next. This method of asynchronous communication ensures that the data rate is suited to the slowest active listener, as well as ensuring compatibility over a wide range of devices.

The remainder of this manual assumes working familiarity with the IEEE-488 1975/78 standards. Terminology and abbreviations defined within these standards are freely used throughout. The IEEE convention of lower case for local messages and upper case for remote messages (received via the interface) is used in all acronyms.

1.5 TYPICAL APPLICATIONS

The TMS9914A is used when an intelligent instrument is required to communicate with an IEEE-488 General Purpose Interface Bus (GPIB). It performs the interface function between the microprocessor and bus and relieves the processor of the task of maintaining the IEEE protocol. By utilizing the interrupt capabilities of the device, the bus does not have to be continually polled, and fast responses to changes in the interface configuration can be achieved.

A block diagram showing the TMS9914A in a typical application is given in Figure 1-1.

The GPIB input/output pins are connected to the IEEE-488 bus via bus transceivers. The direction of data flow is controlled by the TE and CONT outputs generated on the TMS9914A. The SN75160, 75161 and 75162 (see Appendix C) are designed specifically for use with a GPIB interface. The TE and CONT signals are routed within the devices so that the buffers on particular lines are controlled as required by the TMS9914A. Other buffers may be used, but they may require a small amount of external logic, particularly around the EOI line buffer.

Communication between the microprocessor and TMS9914A is carried out via memory-mapped registers. There are 13 registers within the TMS9914A, 6 of which are read and 7 write. These registers both pass control data to and get status information from the device.

The three least significant address lines from the MPU are connected to the register select lines RSO, RS1, and RS2 and determine the particular register selected. The high order address lines are decoded by external logic to cause the \overline{CE} input to the TMS9914A to be pulled low when any one of eight consecutive addresses are selected. Thus the internal registers appear to be situated at eight consecutive locations within the MPU address space. Reading or writing to these locations transfers information between the TMS9914A and the microprocessor. Note that reading and writing to the same location will not access the same register within the TMS9914A since they are either read-only or write-only registers. For example, a read operation with RS2-RSO = 011 gives the current status of the GPIB interface control lines, whereas a write to this location loads the auxiliary command register.

Each device on the bus interface is given a 5-bit address enabling it to be addressed as a talker or listener. This address is set on an external DIP switch (usually at the rear of an instrument) before power-on.

FIGURE 1-1 - TYPICAL TMS9914A APPLICATION

Typical TMS9914A configuration utilizes registers 100 or 101 as an address switch register (see Table 2-1). This register may consist of a DIP switch which drives the data lines via tristate buffers when one of these addresses is read. This allows the host MPU to read a device address which is manually set and write this address into the address register of the TMS9914A for device identification on the bus. The TMS9914A responds by causing a My Address (MA) interrupt and entering the required addressed state when this address is detected on the GPIB data lines.

2. ARCHITECTURE

The block diagram of the internal architecture of the TMS9914A is given in Figure 2-1. As previously stated, there are 13 MPU accessible registers of which 6 are read and 7 are write. These registers handle all communication between the IEEE-488 1975/78 bus and microprocessor.

Each register is accessed by putting the relevant address on lines RSO, RS1 AND RS2 and performing a memory read ($\overline{WE} = 1 \text{ DBIN} = 1$) or memory write ($\overline{WE} = 0 \text{ DBIN} = 0$) operation. The register addresses and use of each bit is shown in Table 2-1 for the read registers and Table 2-2 for the write registers. A full description of each register is given in the following paragraphs.

Implementation of the functions described by the state diagrams of the IEEE-488 standard is carried out in the IEEE-488 state diagram block. Information is received from the IEEE bus and from the internal registers and is combined with the current status of the device (for example, Talker Active State, TACS) to produce the control signals to load registers or handle the handshake or bus management lines.

FIGURE 2-1 - SIMPLIFIED BLOCK DIAGRAM

TABLE 2-1 - TMS9914A READ REGISTERS

A	ADDRESS		DECICIER NAME		BIT ASSIGNMENT

*This address is not decoded by the TMS 9914A. A write to this location will have no effect on the device, as if a write had not occurred.

2.1 REGISTERS

2.1.1 Interrupt Mask and Status Registers 0

The Interrupt Mask and Interrupt Status registers operate independently of each other. The status bits will always be set when the appropriate events occur regardless of the state of the corresponding mask bit.

All interrupt bits, with the exception of INTO and INT1 which are not storage bits, are edge triggered and are set when the appropriate condition becomes true. The storage bits are cleared immediately after the corresponding Interrupt Status Register is read by the host MPU. If an interrupt condition becomes true during this read operation, then the event is stored. The corresponding bit is set when the read operation ends, hence no interrupts are lost. In addition to being cleared by a read operation, the BO interrupt is also cleared by writing to the Data Out Register, and the BI interrupt is cleared by reading the Data In Register.

The interrupt status bits are cleared and held in the O condition while Software Reset (swrst) is set.

The corresponding bit of the Interrupt Mask register must be set to a 1 if an interrupt status bit is to cause an external interrupt (\overline{INT} Low) when it is set (i.e., $\overline{INT} = \overline{INT}$ STATUS.INT MASK). The mask register is not cleared by 'swrst' or the Hardware Reset pin (\overline{RESET}) and will power on in a random state. It must, therefore, be written to by the host MPU before 'swrst' is cleared to avoid extraneous interrupts (see Section 2.1.6 for operation of 'swrst').

The INTO and INT1 bits of the Interrupt Status Register are not true status bits. INT1 will be true if there are any unmasked interrupt status bits set to a 1 in Interrupt Status Register 1. INTO will be true if any of bits 2-7 of Interrupt Status Register 0 are unmasked and set to a 1. If either INT1 or INT0 is true, then the external interrupt pin (INT) will be pulled low provided that the Disable All Interrupts feature (dai) has not been set.

The individual bits of Interrupt Status and Interrupt Mask Register 0 are described are in the following paragraphs. The conditions which set these bits, shown in parentheses, are given in terms of the state diagrams described in Section 3. Each bit is set on the rising edge of the condition shown.

INTERRUPT MASK/STATUS REGISTER 0

xx	xx	BI	во	END	SPAS	RLC	MAC	INT	MASK O
ΙΝΤΟ	INT1	ВІ	во	END	SPAS	RLC	MAC	INT	STATUS 0
DO	D1	D2	D3	D4	D5	D6	D7		MPU BUS

NOTE: A 0 masks and a 1 unmasks the bits in the interrupt mask registers.

INT1 This will be a 1 when an unmasked status bit in Interrupt Status Register 1 is set to a 1.

INTO This will be a 1 when any of bits 2-7 of Interrupt Status Register 0 is unmasked and set to a 1.

- BI Byte In. A data byte has been received in the Data In register. If the mask bit is not set, then no interrupt is generated but a RFD holdoff will still occur before the next data byte is accepted. If the Shadow Handshake feature is used, then this status bit will not be set. This bit is cleared by reading the Data In Register as well as after Interrupt Status Register 0 has been read. (Set On: ACDS1.LACS)
- BO Byte Out. This is set when the Data Out Register is available to send a byte over the GPIB. This byte may be either a command if the device is a controller or data if the device is a talker. It is set when the device becomes an active talker or controller but will not occur if the Data Out register has been loaded with a byte which has not been sent. Subsequently, it will occur after each byte has been sent and the TMS9914A returns to SGNS. This bit is cleared by writing to the Data Out Register as well as by reading Interrupt Status Register 0.

(Set On: SGNS.CACS + SGNS.TACS.SHFS)

NOTE

When a controller addresses itself as a talker and then goes to standby, there will be a momentary transition of the source handshake into SIDS before TACS becomes true and it reenters SGNS. Under these circumstances, the TMS9914A is guaranteed to give a BO interrupt on reentering 'SGNS'. The TMS9914, however, may not, and a controller going to standby as a talker should write the first byte of data into the Data Out Register immediately after writing the gts auxiliary command, without waiting for a BO interrupt (see Appendix B for details).

- END This indicates that a byte just received by a listener was the last byte in a string, that is, it was received with the EOI line true. It is set at the same time as the BI interrupt. (Set On: (ACDS1.LACS.EOI)
- SPAS This indicates that the TMS9914A has requested service via rsv1 or rsv2 (in the Serial Poll Register or Auxiliary Command Register) and has been polled in a serial poll. It is set on the false transition of STRS when the serial poll status byte is sent. (Set On: STRS.SPAS.(APRS1 + APRS2)
- RLC Remote/Local Change. This is set by any transition between local and remote states in the Remote/Local function. (Set On: (LOCS-REMS) + (REMS-LOCS) + (LWLS-RWLS) + (RWLS-LWLS)
- MAC My Address Change. This indicates that a command has been received from the GPIB which has resulted in the addressed state of the TMS9914A to change. It will not occur if secondary addressing is being used, nor indicate that the TMS9914A has been readdressed on its other primary address. (Set On: ACDS1.(MTA.TADSUNT + OTA.TADS + MLA.LADS + UN.LADS)

2.1.2 Interrupt Mask and Status Registers 1

The operation of Interrupt Mask and Status Register 1 is similar to that of Interrupt Mask and Status Register 0 except that all bits are true storage bits. The status bits are cleared only following the register being read and by 'swrst'.

There is one distinct group of interrupts in this register: GET, UNC, APT, DCAS, MA. These are all set in response to commands received over the bus and if unmasked, a Data Accepted (DAC) holdoff will occur when the interrupt in question is set. It may be released with a 'dacr' auxiliary command. This is further discussed in Section 3.2.

The mask bit of the APT interrupt is further used in the talker and listener functions. When the interrupt is unmasked, the talker and listener functions of the TMS9914A implement the extended talker and extended listener functions of IEEE-488. Otherwise these functions implement the talker and listener functions of IEEE-488.

The individual bits of Interrupt Status and Interrupt Mask Register 1 are described below. The conditions which set these bits, shown in parentheses, are given in terms of the state diagrams described in Section 3.

GET	ERR	UNC	APT	DCAS	MA	SRQ	IFC	INT	MASK 1
GET	ERR	UNC	ΑΡΤ	DCAS	MA	SRQ	IFC	INT	STATUS 1
DO	D1	D3	D3	D4	D5	D6	D7	MPU	BUS

INTERRUPT MASK/STATUS REGISTER 1

GET

This is set if a Group Execute Trigger command is received. A DAC holdoff occurs if the interrupt is unmasked. The TR pin becomes high when this command is received and persists high for the duration of a DAC holdoff if one occurs. If the interrupt is masked, the TR pin becomes high for approximately five clock cycles.

(Set On: GET.LADS.ACDS1)

- ERR Error. This is set if the source handshake becomes active and finds that the NDAC and NRFD lines are both high. This indicates that, for whatever reason, there are no acceptors on the bus. (Set On: SERS)
- UNC Unrecognized Command. This is set if a command has been received which has no meaning to the TMS9914A. Unrecognized addressed commands will only cause this interrupt if the device is LADS except for TCT which will only interrupt in TADS. Secondary commands will only cause this interrupt if the 'pts' auxiliary command has been set previously. A DAC holdoff will occur if this interrupt is unmasked which effectively enables the command pass through feature. Unrecognized commands may be inspected in the Command Pass Through Register before this holdoff is released. (Set On: ACDS1.(UCG.LLO.SPE.SPD.DCL + ACG.GET.GTL.SDC.TCT.LADS + TCT.TADS + SCG.pts))
- APT Address Pass Through. Unmasking this interrupt enables secondary addressing. It is set if a secondary command is received provided that the last primary command received was a primary talk or listen address of the TMS9914A. A DAC holdoff will occur and the secondary address may be read from the Command Pass Through Register. The holdoff may be released by a 'dacr' auxiliary command and the 'cs' bit of the Auxiliary Command Register is used to indicate that a valid (cs = 1) or an invalid (cs = 0) secondary has been identified by the host MPU. (Set On: ACDS1.SCG.(LPAS + TPAS))
- DCAS Device Clear Active State. This is set when a device clear command (DCL) is received or when a selected device clear (SDC) is received with the TMS9914A in LADS. This will cause a DAC holdoff if unmasked. (Set On: ACDS1.(DCL+SDC.LADS))
- SRQ Service Request. This is provided for the benefit of the controller which should execute a serial poll in response to this interrupt. It is set when the SRQ line becomes true. (Set On: SRQ.(CIDS + CADS))
- MA My Address. This is set when the TMS9914A recognizes its primary talk or listen address. A DAC holdoff will occur if this is unmasked. (Set On: (MLA + MTA).SPMS.aptmk))
- IFC Interface Clear. This is provided for the benefit of devices which are not the System Controller. It is set when the IFC line becomes true and indicates that the TMS9914A has been returned to an idle state. If the device is the System Controller, then the IFC interrupt is not set. (Set On: IFCIN)

REM	LLO	ATN	LPAS	TPAS	LADS	TADS	ulpa		
DO	D1	D2	D3	D4	D5	D6	D7	MPU BUS	
RFM The device is in the remote state									

LLO	Local lockout is in operation
ATN	The attention line is low (true) on the bus
LPAS	TMS9914A is in the listener primary addressed state
TPAS	TMS9914A is the talker primary addressed state
LADS(or LACS)	The device is addressed to listen
TADS(or TACS)	The device is addressed to talk
ulpa	This bit shows the LSB of the last address recognized by the TMS9914A.

2.1.4 Address Register

edpa	dal	dat	A5	A4	A3	A2	A1
DO	D1	D2	D3	D4	D5	D6	D7

edpaEnable dual primary addressing modedalDisable listener functiondatDisable talker functionA5-A1Primary address of the TMS9914A

Bits A5-A1 of this register contain the primary address of the device (denoted AAAAA in Table 3-15). IEEE-488 1975/78 does not allow a device to be assigned the value 11111 for bits A5-A1. When 'swrst' is true at power-up or if set by the host MPU, the TMS9914A is held in an idle state. During this time the host MPU may load the primary address of the device into these bits. Often this will be read from an Address Switch Register (see Section 1.5).

The 'edpa' bit is used to enable the dual addressing mode of the TMS9914A. It causes the LSB of the address to be ignored by the address comparator giving two consecutive primary addresses for the device. The address by which the TMS9914A was selected is indicated by the 'ulpa' bit of the Address Status Register.

The Address Register is not cleared by 'swrst' or hardware reset.

2.1.5 Auxiliary Command Register (see Section 3.1 for Auxiliary Command State Diagram)

CS	xx	xx	F4	F3	F2	F1	FO
DO	D1	D2	D3	D4	D5	D6	D7

f4-f0 Auxiliary command select (see Table 2-3)

cs Clear or set the feature (where applicable)

Auxiliary commands are used to enable and disable most of the selectable features of the TMS9914A and to initiate many of the actions of the device. The desired feature is selected by writing a byte to this register with the appropriate value in bits f4-f0. These values are given in Table 2-3.

The 'cs' bit is used in most cases when the feature selected by f4-f0 is of the clear/set type. The feature is enabled if 'cs' = '1' and disabled if 'cs' = '0'. The holdoff on all data (hdfa) feature is an example of such a feature. Other auxiliary commands initiate an action of the TMS9914A, such as release RFD holdoff (rhdf). In most cases, the 'cs' bit is unused and ignored by these commands.

All the clear/set auxiliary commands are cleared by the hardware RESET pin except 'swrst,' which is set true by RESET.

The force group execute trigger (fget) and return to local (rtl) auxiliary commands have a clear/set mode of operation and a pulsed mode of operation. They behave as normal clear/set features, but if they are written with 'cs' = '0' when they have not been previously set, then they will pulse true. Using the 'fget' command in this manner will produce a pulse of approximately 1 μ s at the TR pin (with a 5 MHz clock). The 'rtl' command used in this way will cause a return to one of the local states (assuming local lockout is not in force) but the TMS9914A may reenter the remote state next time the listen address occurs (see Section 3.6).

c/s	f4	f3	f2	f1	fO	MNEMONIC	FEATURES

TABLE 2-3 – AUXILIARY COMMANDS

2.1.6 Description of Auxiliary Commands

Software Reset (swrst) 0/1xx00000

Setting this command causes the TMS9914A to be returned to a known idle state during which it will not take part in any activity on the GPIB. This auxiliary command is set by the power-on RESET and the chip should be configured while 'swrst' is set. Configuration should include writing the address of the device into the Address Register, writing mask values into the Interrupt Mask Registers and selecting the desired features in the Auxiliary Command Register and Address Register. After this, 'swrst' may be cleared at which point the device becomes logically existent on the GPIB. The Serial Poll Register and Parallel Poll Registers may also be written in this period but this is not necessary if there is no status to report as both of these are cleared by the power-on RESET pin. Table 2-4 lists the various states and other conditions forced by 'swrst'.

TABLE 2-4 – SOFTWARE RESET CONDITIONS

MNEMONIC	DESCRIPTION
SIDS	Source idle state
AIDS	Acceptor idle state
TIDS	Talker idle state
TPAS	Talker primary idle state
LIDS	Listener idle state
LPAS	Listener primary state
NPRS	Negative poll response state
LOCS	Local state
CIDS	Controller idle state
SPIS	Serial poll idle state
PPSS	Parallel poll standby state
ADHS	DAC holdoff state
AEHS	RFD holdoff on end state
SHFS	Source holdoff state
ENIS	END idle state

NOTES: 1. See Section 3 for definition of above.

2. All interrupt status bits are held in a O state, but interrupt mask bits are not affected.

Release DAC Holdoff (dacr)0/1xx00001

The Data Accepted (DAC) holdoff allows time for the host microprocessor to respond to unrecognized commands, secondary addresses, and device trigger or device clear commands. The holdoff is released by the MPU when the required action has been taken. Normally the command is loaded with the clear/set bit at zero; however, when used with the address pass through feature CS is set to one if the secondary address was valid or to zero if invalid (see APT interrupt in Section 2.1.2).

Release RFD Holdoff (rhdf)naxx00010

Any Ready For Data (RFD) holdoff caused by a 'hdfa' or 'hdfe' is released.

Holdoff on All Data (hdfa) 0/1xx00011

A Ready For Data (RFD) holdoff is caused on every data byte until the command is loaded with CS set to zero. The handshake must be completed after each byte has been received by the MPU using the 'rhdf' command.

Holdoff on End (hdfe)0/1xx00100

A RFD holdoff will occur when an end of data string message (EOI true with ATN false) is received over the interface. This holdoff must be released using 'rhdf'.

Set New Byte Available False (nbaf)naxx00101

If a talker is interrupted before the byte just stored in the data out register is sent over the interface, this byte will normally be transmitted as soon as the ATN line returns to the false state. If, as a result of the interrupt, this byte is no longer required, its transmission may be suppressed using the 'nbaf' command.

Force Group Execute Trigger (fget)0/1xx00110

The state of the TR output from the TMS9914A is affected when this command is executed. If the CS bit is zero, the line is pulsed high for approximately 5 clock cycles (1 μ s at 5 MHz). If CS is one, the TR line goes high until 'fget' is sent with CS equal to zero. No interrupts or handshakes are initiated.

Return to Local (rtl)0/1xx00111

Provided the local lockout (LLO) has not been enabled, the remote/local status bit is reset, and an interrupt is generated (if enabled) to inform the host microprocessor that it should respond to the front panel controls. If the CS bit is set to one the 'rtl' command must be cleared (CS = 0) before the device is able to return to remote control. If CS is set to zero, the device may return to remote without first clearing 'rtl'.

Force End or Identify (feoi) naxx01000

This command causes the EOI message to be sent with the next data byte. The EOI line is then reset.

Listen Only (Ion) 0/1xx01001

The listener state is activated until the command is sent with CS set to 0 or until deactivated by a bus command.

Talk Only (ton) 0/1xx01010

The talker state is activated until the command is sent with CS set to 0 or until deactivated by a bus command.

NOTE

'ton' and 'lon' are included for use in systems without a controller. However, where the TMS9914A is being used as a controller, it utilizes the 'lon' and 'ton' functions to set itself up as a listener or talker, respectively. Care must therefore be taken to ensure these functions are reset if sending UNL or OTA.

Go to Standby (gts)naxx01011

Issued by the controller in charge to set the ATN line false.

Take Control Synchronously (tcs)naxx01101

Control is again taken by the controller in charge, and ATN is asserted. If the controller is not a true listener, the shadow handshake command must be used to monitor the handshake lines so that the TMS9914A is synchronous with the talker/ listeners and only sends ATN true at the end of byte transfer. This ensures that no data is lost or corrupted.

Request Parallel Poll (rpp)0/1xx01110

This is executed by the controller in charge to send the parallel poll command over the interface (the TMS9914A must be in the Controller Active State so that the Attention line is asserted). The poll is completed by reading the Command Pass Through Register to obtain the status bits, then sending 'rpp' with the CS bit at zero.

Take Control Asynchronously (tca)naxx01100

This command is used by the controller in charge to set the attention line true and to gain control of the interface. The command is executed immediately and data corruption or loss may occur if a talker/listener is in the process of transferring a data byte.

Send Interface Clear (sic)0/1xx01111

The IFC line is set true when this command is sent with CS set to one. This must only be sent by the system controller and should be reset (CS = 0) after the IEEE minimum time for IFC has elapsed (100 μ s). The system controller is put into the controller active state.

Send Remote Enable (sre)0/1xx10000

Issued by the system controller to set the REN line true and send the remote enable message over the interface, REN is set false by sending 'sre' with CS at zero.

Request Control (rqc)naxx10001

When the TCT command has been recognized via the unidentified command pass through, this command is sent by the MPU. The TMS9914A waits for the ATN line to go false and then enters the controller active state (CACS).

Release Control (ric)naxx10010

This command is used after TCT has been sent and handshake completed to release the ATN line and pass control to another device.

Disable All Interrupts (dai)0/1xx10011

The INT line is disabled, but the interrupt registers and any holdoffs selected are not affected.

Pass Through Next Secondary (pts)naxx10100

This feature may be used to carry out a remote configuration of a parallel poll. The parallel poll configure command (PPC) is passed through the TMS9914A as an unrecognized addressed command and is identified by the MPU. The 'pts' command is loaded, and the next byte received by the TMS9914A is passed through via the Command Pass Through Register. This would be the parallel poll enable (PPE), which is read by the microprocessor.

Set T1 Delay (std1)1xx10101

The T1 delay time can be set to 6 clock cycles (1.2 μ s at 5 MHz) if this command is sent with the CS bit at one. The TI delay time is 11 clock cycles (2.2 μ s at 5 MHz) following a power-on reset or if the command is sent with CS set to zero.

Shadow Handshake (shdw)0/1xx10110

This feature enables the controller in charge to carry out the listener handshake without participating in a data transfer. The Data Accepted line (DAC) is pulled true a maximum of 3 clock cycles after Data Valid (DAV) is received, and Not Ready For Data (NRFD) is allowed to go false as soon as DAV is removed.

The shadow handshake function allows the 'tcs' command to be synchronized with the Acceptor Not Ready State (ANRS) so that ATN can be re-asserted without causing the loss or corruption of data byte. The END interrupt can also be received and causes a RFD holdoff to be generated.

Very Short T1 Delay (vstd1)0/1xx10111

If this feature is enabled, the GPIB settling time (T1) will be reduced to 3 clock cycles (600 ns at 5 MHz) on the second and subsequent data bytes when ATN is false. Otherwise, the GPIB settling time is determined by the std1 feature.

Request Service Bit 2 (rsv2)0/1xx11000

The rsv2 bit performs the same function as the rsv1 bit (see Section 2.1.8) but provides a means of requesting service which is independent of the Serial Poll Register.

This allows minor updates to be made to the Serial Poll Register without affecting the state of the request service.

In addition, rsv2 is cleared when the serial poll status byte is sent to the controller during a serial poll. It is therefore used in situations where a service request is simply a request from an instrument for the controller to poll its status. As soon as this happens, rsv2 is cleared since the reason for requesting service has been satisfied. This eliminates the burden of clearing the bit from the host MPU but also guarantees that rsv2 is cleared before another serial poll can occur. If this were not so, there would be a possibility of a second status byte being sent with the RQS message true, which could result in confusion for the controller. (rsv2 is cleared on: SPAS.(APRS1 + APRS2).STRS). It should be noted that the vstd1 and rsv2 features were not present on the TMS9914.

2.1.7 Bus Status Register

]	REN	IFC	SRQ	EOI	NRFD	NDAC	DAV	ATN
- MP(D7	D6	D5	D4	D3	D2	D1	DO

The host MPU may examine the status of the GPIB management lines at the time of reading.

The IFC bit of this register does not indicate a true value if the device is a system controller using the 'sic' auxiliary command.

2.1.8 Serial Poll Register

S8	rsv1	S6	S5	S4	S3	S2	S1	
D108	D107	D106	DI05	DI04	DI03	DI02	DI01	GPIB
DO	D1	D2	D3	D4	D5	D6	D7	MPU BUS

S8, S6-S0 Device status

rsv1 Request service bit 1

Bits S8, S6-S1 of this register are sent out over the GPIB when the device is addressed during a serial poll. They are cleared by a hardware reset but not by 'swrst' and may therefore be set up during configuration of the chip. These bits are fully double buffered and if the register is written to while the device is addressed during a serial poll (serial poll active state, SPAS), the value written is saved, and these bits are updated when SPAS is terminated.

The rsv1 bit provides an input to the service request function of the TMS9914A and is used to instruct this to request that the controller service the device. When rsv1 is set true, the SRQ line is pulled true on the GPIB, and the controller typically responds by setting up a serial poll to obtain the status of all instruments on the bus that may require service. When the TMS9914A is addressed to send its status byte, SRQ is set false, and the status byte is sent with the RQS message true on DIO7. The rsv1 bit must then be cleared and set true again if service is to be requested a second time. The SPAS interrupt is set immediately following the status byte being sent.

The rev1 bit is also cleared by the hardware reset pin but not by 'swrst'. It is not double-buffered but the service request function comprehends changes in the state of rsv1 while the device is in SPAS. The Serial Poll Register may therefore be written to any time. Section 3.5 contains more information on the service request function. Note that the rev1 bit of the TMS9914 was simply referred to as 'rsv' since this device did not have an rsv2 auxiliary command.

2.1.9 Command Pass Through Register

DIO8	DI07	DI06	D105	D104	D103	DI02	DIO1	GPIB
DO	D1	D2	D3	D4	D5	D6	D7	MPU BUS

This provides a means of directly inspecting the GPIB data lines (DIO(8-1)). It has no storage and should only be used when the data lines are known to be in a steady state such as will occur during a DAC holdoff or in CPWS during a parallel poll. It is used to read unrecognized commands and secondaries following a UNC interrupt or to read secondary addresses following an APT interrupt. In addition, an active controller uses this register to read the results of a parallel poll at least 2μ s after setting the 'rpp' auxiliary command.

2.1.10 Parallel Poll Register

	PP1	PP2	PP3	PP4	PP5	PP6	PP7	PP8
GPIB	DI01	DI02	DI03	DI04	D105	DI06	DI07	DI08
MPU BUS	D7	D6	D5	D4	D3	D2	D1	DO

When a controller initiates a parallel poll, the contents of this register are presented to the GPIB data lines. If all bits of the register are cleared, then none of the lines DIO(8-1) will be pulled low during a parallel poll which corresponds to the Parallel Poll Idle State (PPIS) of IEEE-488. If it is desired to participate in a parallel poll, then the bit corresponding to the desired parallel poll response is set to a 1.

The Parallel Poll Register is fully double buffered. If it is written to during a parallel poll, the new value is held until the parallel poll ends, at which point the register is updated. This permits the host MPU to update the parallel poll response completely asynchronously to the GPIB.

If this register is cleared by the hardware RESET pin but not by 'swrst,' it may be loaded while the chip is being configured with 'swrst' set.

2.1.11 Data In Register

DIO8	DI07	DI06	DI05	DI04	DI03	DIO2	DIO1	GPIB
DO	D1	D2	D3	D4	D5	D6	D7	MPU BUS

This register is used to hold data received by the TMS9914A when it is a listener. It is loaded during Accept Data State (ACDS1) and, following this, an RFD holdoff will occur. This will normally be released when the byte is read by the host MPU, but if the Holdoff On All Data (hdfa) feature is selected, this holdoff must be released by the 'rhdf' auxiliary command.

If the Holdoff On End (hdfe) feature is selected, the RFD holdoff will be released by reading the Data In Register. But if the EOI line is true when the byte is received, reading the data byte will not release the holdoff and rhdf must be used.

As the Data In Register is loaded, the BI interrupt is set. The END interrupt is set simultaneously if the byte is accompanied by a true EOI line.

2.1.12 Data Out Register

D108	DI07	DI06	DI05	DI04	DI03	D102	DI01	GPIB
DO	D1	D2	D3	D4	D5	D6	D7	MPU BUS

The Data Out register is used by a controller or talker for sending interface messages and device dependent messages. When the TMS9914A enters the Talker Active State (TACS) or the Controller Active State (CACS), the contents of the Data Out Register are presented to the GPIB data lines (DIO(8-1)), and the byte is sent over the bus under the control of the Source Handshake. Each time a byte is written, the source handshake is enabled, and the byte is sent. If the handshake is interrupted before the byte can be sent, then it will be sent next time the Source Handshake becomes active unless a new byte available false (nbaf) auxiliary command is written. This has the effect of clearing an unsent byte from the Data Out Register, and although the register itself is not cleared, the TMS9914A behaves as if it had not been loaded.

Each time the source handshake becomes active and there is no unsent byte in the Data Out Register, a BO interrupt will occur informing the host MPU that the Data Out Register is available for use.

The Data In Register and Data Out Register operate independently. The Data Out Register is not double buffered, and its contents are output directly to the data lines of the GPIB.

2.2 DIRECT MEMORY ACCESS

The TMS9914A can operate in DMA using the ACCRQ (DMA request) and ACCGR (DMA grant) DMA handshake lines. The operation is automatic within the TMS9914A and needs no 'mpu' configuration.

The ACCRQ signal is set by (BO.CACS + BI) and can therefore not be used by a controller while ATN is asserted. It is reset by 'swrst' readin data in register, writing to the data out register and ACCGR. It is not cleared by reading interrupt status register 0.

If using DMA, the internal CE and addressing is disabled by the \overline{ACCGR} signal going low and \overline{ACCGR} will automatically address either the data in register (DBIN = 0) or the data out register (DBIN = 1).

NOTE

The sense of DBIN is inverted for DMA operation.

At the end of a DMA read from memory sequence, the ACCRQ will be left low (also BO bit set). It may be necessary for the 'mpu' to clear this in some circumstances, e.g., starting DMA write to memory sequence.

In DMA it is recommended that the MA interrupt be unmasked to prevent errors due to interrupted data streams.

If DMA is not being utilized, the \overline{ACCGR} signal must be held high. In this case, the \overline{ACCRQ} signal can be used as a separate interrupt line for BO and BI. This allows faster 'mpu' transfers to take place as it is not necessary to read the interrupt register to find the cause of the interrupt. Figure 2-2 shows a typical DMA configuration.

2.3 TERMINAL ASSIGNMENTS AND FUNCTIONS

The IEEE-488 standard uses the negative logic convention for the GPIB lines. The FALSE state (0) is represented by a high voltage (> 2.0 V); the TRUE state (1) is represented by a low voltage (> 0.8 V). The GPIB terminations of the TMS9914A are in agreement with this convention. For example, if Data Valid is true (1), the DAV line is pulled low by the device. These terminations are connected to the bus via noninverting buffers to obtain the correct signal polarity.

Note that the terminations on the microprocessor side of the device are in positive logic (true state (1) = high voltage : false state (0) = low voltage). This is in agreement with the logic convention used by most microprocessors. Thus if:

DO(MSB)							D7(LSB)
0	1	1	0	1	0	0	1

is written into the data out register, it will appear as:

DIO8(MSB)

DIO1(LSB)

	HIGH	LOW	LOW	HIGH	LOW	HIGH	HIGH	LOW
--	------	-----	-----	------	-----	------	------	-----

on the IEEE-488 D10 lines.

FIGURE 2-2 - DMA CONFIGURATION

RS1	7	1	which register is addressed by the	
RS2	8	I.	MPU during a read or write operation.	

TERMINAL ASSIGNMENTS AND FUNCTIONS (continued)

SIGNATURE	PIN	I/O (TYPE)	DESCRIPTION	
CE	3	I	CHIP ENABLE: CE low allows access of read	
			and write registers. If CE is high, D0-D7 are	
			in high impedance unless ACCGR is low.	
WE	4	. I .	WRITE ENABLE: when active (low), in-	
			dicates to the TMS9914A that data is being	
an agus an a			written to one of its registers.	
DBIN	5	1	DATA BUS IN: an active (high) state in-	
			dicates to the TMS9914A that a read is	
			about to be carried out by the MPU.	
INT	9	O(o/d)	INTERRUPT: sent to the MPU to cause a	
		(no pullup)	branch to a service routine.	
ACCRO	1	O(p/p)	ACCESS REQUEST: this pin becomes active	
			(low) to request a direct memory access.	
ACCGR	2	1	ACCESS GRANTED: when received from the	
			direct memory access control logic this	
			enables the byte onto the data bus. ACCGR	
			must be high when not participating in DMA	
			transfer.	
RESET*	19	1	INITIALIZES the TMS9914A at power-on.	
TR	39	O(p/p)	TRIGGER: activated when the GET com-	
			mand is received over the interface or the	
			fget command is given by the MPU.	
ō	18	1	CLOCK input: 500 kHz to 5 MHz. Need not	
			be synchronous to system clock.	
V _{SS}	20		Ground reference voltage.	
Vcc	40		Supply voltage (+5 V nominal).	

(p/p) = push/pull output.

(o/d) = open drain output with internal pull up.

The hardware RESET pin has the following effect on the TMS9914A:

Serial and Parallel Poll registers cleared

- All clear/set auxiliary commands cleared except 'swrst'

- 'swrst' auxiliary command set. This holds the TMS9914A in known states, as described in Section 2.1.6.

2.4 TRANSCEIVER CONNECTIONS

There are three linear transceivers designed to work with the TMS9914A: the SN75160, SN75161, and SN75162. Data sheets for these are included as Appendix C. Figure 2-3 shows the possible transceiver connections. Note that there is a corresponding pinout between the TMS9914A and the transceivers. This allows the whole GPIB interface to be laid out in a very small area of printed circuit board.

The SN75160 is a 20 pin device used to buffer the IEEE-488 data lines (DIO(8-1)) in all applications. The direction of the buffers is controlled by the Talk Enable (TE) output of TMS9914A. This active high signal becomes true whenever there is an interface function of the TMS9914A not sending the NUL message on DIO(8-1), that is, when the device is in TACS, CACS, SPAS, or PPAS. The Pull-Up Enable (PE) input of the SN75160 is an active high input which selects whether the 'DIO(8-1)' lines are driven by open collector or push/pull buffers. A push/pull buffer is required if faster data rates are required and the 'stdl' and/or the 'vstdl' features are used. Open collectors must be used if parallel polling is being used in a particular GPIB environment. If only one of these features is desired the PE input may be hardwired otherwise it must be derived from ATN and EOI, as shown in Figure 2-3.

The SN75161 is a 20-pin device used to buffer the IEEE-488 management lines. It may be used for a talker/listener device or for a controller which does not pass control. The direction of the handshake line buffers NRFD, NDAC, DAV are again controlled by the TE signal. However, the SRQ, ATN, REN, and IFC buffers are controlled by the DC input of the SN75161, which connects to the Controller Active (CONT) output of the TMS9914A. CONT becomes low whenever the TMS9914A is an active controller, that is, when it is not in CIDS or CADS. The SN75161 also includes the logic necessary to control the direction of the EOI buffer. This is dependent on the TE signal when ATN is false (high) and the DC signal when ATN is true (low).

The SN75162 is a 22-pin device which may be used to buffer the IEEE-488 management lines in all applications including devices which pass control. The SN75162 has a separate pin to control the direction of the REN and IFC buffers, but is otherwise identical to the SN75161 in all other respects. This input is the System Controller input (SC) which may be hardwired or switchable to determine whether or not the instrument in question is a system controller or not. Note that a device which has its buffers configured as a non-system controller should never use the 'sic' and 'sre' auxiliary commands for reasons explained in Section 3.8.3.

3. STATE DIAGRAM IMPLEMENTATION

This section presents the state diagrams for the TMS9914A.

Where equivalent, the names of TMS9914A states are the same as those of IEEE-488. In some cases, IEEE-488 states have been divided, for example, ACDS of the IEEE-488 has been split into ACDS1 and ACDS2. The convention of lower case characters for local messages and upper case for remote messages and interface states is retained.

State diagrams with remote message outputs are supplemented with tables. T is used to represent a true output and F a false output. Parentheses denote a passive output; otherwise, it is active. The outputs shown are the values presented to the bus and assume the use of the SN75160 and SN75161 or SN75162 transceivers or their logical equivalents. The symbol (NUL) associated with DIO(1-8) indicates that each of these lines is sent passive false by the function in question.

NOTE

An arrow into a state with no state as its origin represents a transition from every other state on the diagram. Note, however, that this does not imply that all exit conditions from the destination state are overridden. If such an entry condition is true and, simultaneously, an exit condition is true then this represents an illegal situation and should be avoided. Such situations will not occur in normal operation of the device.

No maximum timings are discussed. The TMS9914A with its recommended transceivers meets all IEEE-488 maximum timing requirements as may be determined from Section 4.4 and Appendix C. If the TMS9914A is used with other transceivers, then it must be ensured that these requirements are still met.

3.1 AUXILIARY COMMANDS

There are two basic types of commands implemented in the auxiliary command register: immediate execute and clear/set.

The clear/set commands are used to enable and disable the various features of the TMS9914A. The particular feature is selected by the code on f0-f4 (see Section 2.1.6) and it is set or cleared according to the value on the cs bit. For the purposes of the state diagrams, the mnemonic of a clear/set command simply represents its current state.

The immediate execute auxiliary commands remain active for the duration of a strobe signal after the auxiliary command register has been written to. This is represented in the form of a state diagram in Figure 3-1. Note that writes to the auxiliary command register must be spaced by at least five clock cycles. For the purposes of the remaining state diagrams, the immediate execute commands are represented as the mnemonic gated by the auxiliary command strobe state (AXSS).

The clear/set bit of the auxiliary command register is used by several of the immediate execute commands, for example, 'dacr' uses it to differentiate between valid and not valid secondary addresses when releasing a DAC holdoff on a secondary address. The 'lon' and 'ton' auxiliary commands are also considered immediate execute, as described in Section 3.4.

The 'fget' and 'rtl' auxiliary commands are both immediate execute and clear/set. They may be cleared or set in the normal way, but if they are cleared when they are already in the false state, they will pulse true for the duration of AXSS. In the following state diagrams, however, these are simply included in their clear/set form.

3.2 ACCEPTOR HANDSHAKE

The TMS9914A acceptor handshake is shown in Figure 3-2. The main variation from IEEE-488 to note is that the device remains in AIDS while the controller function is in CACS. The TMS9914A, therefore, does not monitor the commands which it sends over the bus and this places some restrictions on the user which are outlined in Section 3.8.

The accept data state of IEEE-488 (ACDS) is divided into two states. The first, (ACDS1) is used to strobe data into the Data In Register or to sequence the decoding of commands from the bus. All interrupts generated by the acceptor handshake (GET, MA, MAC, DCAS, APT, UCG, BI, and END) are generated by this state. The second (ACDS2) is used as a holding state where the device will remain in the event of a DAC holdoff.

As discussed in Section 2.1.2, certain of the commands will cause interrupts in ACDS1 and, if the interrupts are unmasked, a DAC holdoff will occur. The interrupts concerned are GET, MA, DCAS, UCG, and APT. This is represented in the state diagram by the signal SAHF which becomes true when one of the above interrupts is set if it is unmasked. It persists for the duration of ACDS1. This event is stored by causing the ADHS to become active which inhibits the transition from ACDS2 to AWNS. ADHS is cleared by 'dacr'. Table 3-15 shows the response of the TMS9914A to the various bus commands.

If a GET command is received in ACDS1, then the TR pin will be set high. This high condition persists throughout ACDS1 and ACDS2, which means that if a DAC holdoff occurs, the TR pin will remain high until the holdoff is released by a 'dacr' auxiliary command.

Two additional state diagrams are included to record the type of data received in ACDS1 when ATN is false. ANHS indicates that a data byte has been received and that an RFD holdoff should be caused before the next data byte is accepted. The holdoff may be released by reading the Data In Register unless the 'hdfa' feature is enabled in which case 'rhdf' must be used. AEHS shows that the last data byte was accepted with the EOI message true and the 'hdfe' feature set. This will cause an RFD holdoff which can only be released by 'rhdf'.

3.3 SOURCE HANDSHAKE

The TMS9914A source handshake state diagram is shown in Figure 3-3. IEEE-488 states SIWS and SWNS have been removed. These record the false then true transition of 'nba' (new byte available) as the old data byte is removed and a new data byte is made ready. Instead the TMS9914A uses a separate state (SHFS) to record the availability of a data byte in the Data Out Register. This state is exited when a byte is written to the Data Out Register which enables the transition from SGNS to SDYS and the subsequent transmission of the byte. The SHFS is reentered as the byte is sent in STRS, but if the handshake is interrupted before this, then the fact that the byte has not been sent is recorded until the source handshake again becomes active. If, however, the byte in the data out register is to be disregarded, then 'nbaf' may be used to return the device to SHFS.

The status byte in the Serial Poll Register is continually available. The transition from SGNS to SDYS is not dependent on SHFS during a serial poll, that is, while SPAS is active. By separately recording the availability of a byte in the Data Out Register, a talker sending data may be interrupted for a serial poll without risk of a byte being lost.

The additional state SERS is included to detect an error condition on the bus. This will be entered when the source handshake tries to send a byte but finds both the NRFD and NDAC lines false at the same time. This condition will normally indicate for a controller that there are no devices powered up on the bus, or for a talker that there are no devices addressed to listen on the bus.

The state VSTS will be entered after the first data byte of a talker has been sent if the 'vstdl' feature is enabled. This enables a very short bus settling time $(4t_{C(0)})$ for all subsequent bytes until ATN next becomes true. The TMS9914A will not use the short bus settling time when it is an active controller.

NOTE

The TMS9914 did not implement the 'VSTS'. The bus settling time was therefore either $8t_{c(0)}$ or $12t_{c(0)}$ for 'stdl' set and not set respectively.

3.4 TALKER AND LISTENER FUNCTIONS

Figures 3-4 and 3-5 show the TMS9914A listener and talker state diagrams, which serve the purpose of the listener and talker or extended listener and extended talker functions of IEEE-488, depending on the state of the APT interrupt mask bit.

The TMS9914A does not recognize secondary addresses on-chip and these must be passed through to the host MPU for verification. Secondary addressing is enabled by unmasking the APT interrupt. A secondary address will cause this interrupt if the last primary command received was a primary address of the device, that is, it is in TPAS or LPAS. A DAC holdoff will also occur. The host MPU must respond to the interrupt by reading the secondary from the Command Pass Through Register and identifying it as being valid or not valid. The holdoff may then be released with a 'dacr' auxiliary command, the sense of the 'cs' bit being used to indicate a valid (cs = 1) or not valid (cs = 0) secondary. If a valid secondary address is indicated then the TMS9914A will enter TADS or LADS depending on whether it is in TPAS.

The 'lon' and 'ton' auxiliary commands together with the clear/set bit (cs) have a direct influence on the appropriate state diagrams. Therefore, although they appear as ordinary clear/set auxiliary commands, they can be effectively cleared by other bus events. For example, if a TMS9914A addresses itself as a listener via the 'lon' command it may be returned to LIDS by an UNL command from the bus at a later time.

The 'lon' and 'ton' auxiliary commands are used to implement two features of IEEE-488. First, talk only and listen only are used in situations where there is no active controller on the bus. Note that the 'lon' and 'ton' commands are linked with these features to indicate to the user that these commands are not enabled by CAS as are 'ltn' and 'lun' of IEEE-488.

Second, the 'lon' and 'ton' auxiliary commands are used by an active controller to address itself. IEEE-488 provides for a controller to address itself to listen via the 'ltn' and 'lun' message but there is no corresponding message for the talker. Hence, when a controller addresses itself to talk via 'ton,' it must send its talk address over the bus and similarly, if it sends another talk address over the bus then it must un-address itself by writing 'ton' false.

When the TMS9914A enters SPAS, the contents of the serial poll register are sampled and presented on DIO(8-1). These will remain unchanged until SPAS is exited. The source handshake will, however, send this status byte as many times as the controller will accept it.

The internal IFC signal of the TMS9914A (IFCIN) is suppressed when the device itself is sending IFC in order to simplify implementation of the controller function (see Section 3.8.3). Therefore, the send interface clear (sic) auxiliary command is included with IFCIN to return the talker and listener functions to their idle states and allow a system controller to clear its own interface.

A separate state diagram is included to control the sending of the END message of IEEE-488. If the 'feoi' auxiliary command is written followed by loading a byte into the Data Out Register, the TMS9914A will enter ERAS, and the EOI line will be asserted as 'DIO(8-1)' begin to change. The function will enter ENAS as soon as the source hand-shake begins to send this byte, and EOI will be released when the Data Out Register is next loaded. If it is desired to send EOI true with the next byte as well, then 'feoi' may be written before the Data Out Register returns the device to ERAS.

3.5 SERVICE REQUEST FUNCTION

Figure 3-6 shows the state diagram for the TMS9914A service request function. The device has two means of implementing the request service (rsv) local message of IEEE-488: the first, 'rsv1', is bit 7 of the Serial Poll Register; the second is the auxiliary command 'rsv2'. These are simply ORed together to provide an input to the service request function, and, in any particular application, only one would normally be used, the other being left in its hardware reset state.

The affirmative poll response state (APRS) of IEEE-488 is split into two states on the TMS9914A for the following reason: Consider the case where a device has requested service, has been serial polled, and then wishes to request service again. The host MPU must clear the 'rsv' message and then set it true again. Now suppose this temporary false condition happens within one occurrence of SPAS. If the service request function has been implemented exactly as per IEEE-488, it will not be recognized, and SRQ will not be asserted a second time. Therefore, 'rsv' may only be cleared when the device is known not to be in SPAS, which can only happen if it is cleared as a consequence of some pre-arranged action of the controller. This action would normally be a part of the service routine executed by the controller as a response to the request for service. For example, if service was requested by an instrument which had some data to send for processing or to a printing device then 'rsv' could be cleared when it is addressed to talk and send its data over the bus.

For many applications, the fact that the device has been serial polled after requesting service is considered sufficient response from the controller. The 'rsv' local message therefore simply becomes a request for the controller to read its serial poll status byte. It is then desirable to be able to clear and reassert 'rsv' at any time after the serial poll status byte has been polled and the SPAS interrupt set. The TMS9914A is able to record a false transition of 'rsv1' or 'rsv2' by moving from APRS1 to APRS2 even if the device is in SPAS. This makes the above approach to serial polling possible.

To further support this approach, the 'rsv2' auxiliary command is automatically cleared when the serial poll status byte is polled, ensuring that ''rsv2' is cleared before a second serial poll can occur. If this were not the case, then the same status byte might be polled twice by the controller with the RQS bit true, which may indicate that two reasons for requiring service have arisen.

FIGURE 3-6 - SERVICE REQUEST STATE DIAGRAM

NOTE

The TMS9914 service request function was implemented exactly as per IEEE-488. Also, it had only one 'rsv' bit which was equivalent of the TMS9914A's 'rsv1.'

The TMS9914A will only send one serial poll status byte during each active period of SPAS., However, it will send this status byte as many times as the controller is prepared to accept it. Therefore, the controller should only read the status byte once per serial poll; otherwise, each time a status byte is sent with the RQS message true, the SPAS interrupt will be generated and 'rsv2' will be cleared.

3.6 REMOTE/LOCAL FUNCTION

The TMS9914A remote local state diagram is shown in Figure 3-7. It differs little from that of IEEE-488.

The complete listener function (LAF) is used to effect the transition from LOCS to REMS or from LWLS to RWLS. This means that if the APT interrupt is masked, the device will enter one of the remote states in response to its listen address, but if secondary addressing is enabled, then this will not happen until 'dacr' is written with 'cs' true in response to a valid secondary address. In addition, the transition to one of the remote states will occur if 'lon' is used to address the device to listen.

LAF: See Figure 3-4

3.7 PARALLEL POLL FUNCTION

The parallel poll function of the TMS9914A only nominally supports logically-configured parallel poll. With a suitable software package, remotely-configured parallel poll may also be easily implemented. The state diagram is shown in Figure 3-8.

When the EOI and ATN lines become true simultaneously (the Identify message), the contents of the Parallel Poll Register are output to DIO(8-1). If parallel poll is to be used in a particular bus environment, then the Pull-Up Enable (PE) input of the SN75160 must be held low so that the DIO(8-1) are driven by open collector buffers. Parallel Poll, occurring when the Parallel Poll Register is in the hardware reset condition of all zeros, will result in none of DIO(8-1) being pulled low. This corresponds to the parallel poll idle state (PPIS). If it is desired to participate in a parallel poll, then the bit corresponding to the desired parallel poll response is set true. This implements the parallel poll standby state (PPSS), and, when the Identify message becomes true, the appropriate line of DIO(8-1) is pulled low. This is equivalent to the parallel poll active state (PPAS). Only one bit of the parallel Poll Register should be set true at once.

3.7.1 Remotely Configured Parallel Poll

The parallel poll configure command (PPC) is treated by the TMS9914A as an unrecognized addressed command. It is passed through when the TMS9914A is in LADS. If an instrument is to be remotely configured for parallel poll, then the pass through next secondary (pts) auxiliary command should be written before releasing the DAC holdoff. This will cause the next command received to also set a UNC interrupt if it is a secondary command. The secondary command will be either the parallel poll enable command (PPE) or the parallel poll disable command (PPD) and should be read from the Command Pass Through Register and identified. If it is the PPE command, then the attendant bits (S, P1, P2, P3) should be extracted and stored by the host MPU (see Section 2.9.3 of IEEE-488 1978). The S bit should then be matched against the individual status of the instrument (represented by 'ist'), and if they are the same, the bit corresponding to the parallel poll response, specified by P1, P2, P3, should be set true in the Parallel Poll Register. If this is not the case, then the Parallel Poll Register should be cleared if it is not already clear. After this, each time the individual status of the device changes, the 'ist' should again be matched against the S bit and the Parallel Poll Register updated accordingly until PPD or PPU is received.

If a PPD command is passed through after the 'pts' feature has been written, the Parallel Poll Register should be cleared before the DAC holdoff is released. The PPC command that precedes PPD is an address command; it is a means of eliminating individual members of a parallel poll. The parallel unconfigure command is treated by the TMS9914A as an unrecognized universal command. When it is passed through, the host MPU should clear its Parallel Poll Register before releasing the DAC holdoff. This command will clear all members of a parallel poll.

If there is a true bit in the Parallel Poll Register, it must be sent active; any false bit must be sent passive.

3.8 CONTROLLER FUNCTION

The controller function of the TMS9914A is greatly simplified compared with that of IEEE-488. It relies heavily on software support but, with suitable software, it enables all subsets of the controller function to be implemented. With this approach the controller logic is reduced to a small proportion of the chip area which means that the device may be economically used in situations where a talker/listener only is required.

Figure 3-9 shows the controller function state diagram. With suitable software, it will perform the full controller function, as described in the IEEE-488A 1980 supplement to the IEEE-488 1978. It therefore includes the additional state CSHS, which allows time for DAV to be recognized false by all devices on the bus before ATN is asserted. The 'tcs' local message is implemented by an immediate execute auxiliary command. The state CWAS is therefore added to record the occurrence of this command until the acceptor handshake enters ANRS and the device can enter CSHS. The 'tca' auxiliary command also causes entry into CSHS although IEEE-488A 1980 allows it to move directly from CSBS to CSWS. This is done for convenience of implementation and results in the 'tca' auxiliary command taking an extra 1.6 microseconds to assert ATN.

The delay between CSWS and CAWS is slightly less than specified in IEEE-488A 1980 but the total time taken in moving from CSWS to CACS is still greater than the specified minimum.

The Controller Parallel Poll State (CPPS) is not included on the TMS9914A. To conduct a parallel poll, a TMS9914A based controller must set the 'rpp' clear/set auxiliary command true when it is in CACS, moving it to CPWS which sends EOI true. The host MPU must then wait 2 microseconds before reading back the parallel poll responses via the Command Pass Through Register. The 'rpp' auxiliary command can then be cleared, EOI will go false, and the parallel poll is complete. The host MPU will receive a BO interrupt as soon as the TMS9914A reenters CACS and the source handshake becomes active.

3.8.1 Controller Self Addressing

As discussed in Section 3.2, the acceptor handshake does not operate when the controller is active. This means commands being sent are not monitored, and special precautions are required as a consequence of this when addressing devices and when passing control.

т

Buffers not configured for a system controller; otherwise, buffers are configured for system controller.

When the controller is active, it uses 'ton' or 'lon' to address and unaddress itself. IEEE-488 provides for the controller to locally address itself to listen, but there is no corresponding local message for the talker. The TMS9914A should always accompany a 'ton' auxiliary command with 'cs' true with its own talk address or an UNT command sent over the bus. Similarly, if the TMS9914A sends the talk address of another device over the bus, it should ensure that it is in TIDS by writing the 'ton' auxiliary command false.

Appendix B shows some typical sequences of events when the controller addresses itself, goes to standby, takes control again, etc.

3.8.2 Passing Control

SRAS

As Figure 3-9 shows, the controller transfer state (CTRS) of IEEE-488 is not present, and all transitions associated with the TCT command have been removed. Instead, two immediate execute auxiliary commands are included. Request control (rqc) will cause a transition from CIDS to CADS, and the release control command (rlc) will return the function to CIDS. The TCT command is treated similarly to an unrecognized addressed command but will cause a UNC interrupt if the device is in TADS.

Figure 3-10 is a representation of the sequence of events involved in passing control from one TMS9914A based device to another. The device passing control must initially ensure that it is not in TADS; then it should send out the talk address of the device to receive control. The receiving device will enter TADS, and after any DAC holdoff has been released, the host MPU of the device passing control will set a BO interrupt indicating that it may then send the TCT command. The TCT command will cause a UNC interrupt to the host MPU of the receiving device, and also a DAC holdoff will occur. The host MPU of the receiving device must examine its Command Pass Through Register, and upon identifying TCT, should write the auxiliary command 'rqc' to put its TMS9914A into CADS. The receiving device may then release DAC with a 'dacr' auxiliary command may then be used by the host MPU of the device passing control to return its TMS9914A to CIDS and allowing ATN to go false. The receiving device then enters CACS, asserts ATN, and its host MPU gets a BO interrupt as the source handshake becomes active. The passing of control is complete.

3.8.3 System Controller

The TMS9914A has no on-chip means of determining whether or not it is the system controller. Instead, this is determined by the software and by the configuration of the buffers to the IEEE-488 bus.

FIGURE 3-10 - PASSING CONTROL BETWEEN TMS9914s

The REN and IFC outputs of the TMS9914A are controlled by the auxiliary commands 'sre' and 'sic'. These should never be used by the host MPU of a device unless it is the system controller. As may be seen from Figure 3-11, the REN and IFC outputs of the TMS9914A are open drains with internal pull-ups. This means that the outputs are capable of driving the inputs of the buffers if the device is a system controller. If not, the buffers will drive into the REN and IFC pins and override the pull-ups. Hence, no direction control is required.

The false transition of REN and the true transition of IFC are both debounced to prevent noise on these lines from causing permanent state changes on the TMS9914A. In addition, the internal interface clear signal (IFCIN) is held false if the TMS9914A is sending IFC. Figure 3-9 shows the reason for this. If the device is not a system controller, then the occurence of IFC will return the controller function to CIDS. If, however, the device is a system controller, when it asserts IFC and is in CIDS, the 'sic' auxiliary command will cause it to enter CADS. As IFCIN is suppressed, it will not be forced back into CIDS, and there will be no conflict.

* The REN and IFC signals are at the pins of the TMS9914A and are therefore negative logic signals. The remaining signals are conventional positive logic signals.

FIGURE 3-11 - IFC AND REN PINS

Classes:	UC	-	universal command
	AC	-	addressed command
	AD	-	address
	SE	-	secondary command
Symbols:	0	-	logical zero (high level on GPIB)
	1	-	logical one (low level on GPIB)
	×		don't care (received message)

NOTES: 1. Interrupts listed are as a direct consequence of the command received. They are set during ACDS1 (see Section 3.2) and will cause the INT pin to be pulled low if unmasked.

2. The addressed commands will only cause their corresponding interrupt if the device is in LADS with the exception of TCT.

3. A DAC holdoff will only be caused if the corresponding interrupt is unmasked.

4. AAAAA represents the primary address of a device.

5. SSSSS represents the secondary address of a device.

6. Secondary addresses are handled via address pass through (APT interrupt). The host MPU should respond by writing the 'dacr' auxiliary command with 'cs' false.

7. If OSA is passed through via the APT interrupt, the host MPU should respond by writing the 'dacr' auxiliary command with 'cs' false.

8. PPC is not recognized by the TMS9914A and is therefore treated as an unrecognized addressed command.

9. PPE and PPD are secondary commands. These may be passed through to the host MPU using the 'pts' auxiliary command. When the PPC command is received the 'pts' auxiliary command should be written. PPE or PPD will then cause an APT interrupt.

10. SPPP specifies the sense bit, and the desired parallel poll response ia a remotely configured parallel poll (see Section 3.7.1).

11. DDDD specifies don't care bits which must be sent as zeros but need not be decoded by the host MPU of the receiving devices.

12. PPU is not recognized by the TMS9914A and will cause a UNC interrupt.

13. TCT is not recognized directly by the TMS9914A. It will cause a UNC interrupt when the device is in TADS,

14. RLC is set if MLA or GTL causes an appropriate transition in the Remote/Local function.

4. TMS9914A ELECTRICAL SPECIFICATIONS

4.1 ABSOLUTE MAXIMUM RATINGS OVER OPERATING FREE-AIR TEMPERATURE RANGE (UNLESS OTHERWISE NOTED)*

Supply voltage, V _{CC} (see Note 1)	– 0.3 V to 20 V
All input and output voltages	0.3 V to 20 V
Continuous power dissipation	0.8 W
Operating free-air temperature range	0°C to 70°C
Storage temperature range	– 55 °C to 150 °C

* Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the "Recommended Operating Conditions" section of this specification is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: Under absolute maximum ratings voltage values are with respect to $\mathsf{V}_{\mbox{SS}}.$

4.2 RECOMMENDED OPERATING CONDITIONS

	MIN	NOM	MAX	UNIT
Supply voltage, V _{CC}	4.75	5	5.25	V
Supply voltage, V _{SS}		0		V
High-level input voltage, V _{IH}	2		V _{CC} +1	V
Low-level input voltage, VIL	V _{SS} -0.3		0.8	V
Operating free-air temperature, T _A	0		70	°C

4.3 ELECTRICAL CHARACTERISTICS OVER FULL RANGE OF RECOMMENDED OPERATING CONDITIONS

	PARAME	TER	TEST CONDITIONS	MIN	ΤΥΡ[†] ΜΑΧ	UNIT
Hig Voh	High-level	Except REN,IFC,INT	I _{OH} = -400 μA	2.4	Vcc	v
	output voitage	REN, IFC only	l _{OH} = -100 μA	2.2	Vcc	
VOL	Low-level outp	ut voltage	$I_{OL} = 2 \text{ mA}$	VSS	0.4	V
1	Input current (a	iny input)	$V_{I} = 2 V \text{ to } V_{CC}$		±10	μA
ICC	VCC supply cu	rrent			150	mA
Ci	Input capacitar	ce (any input)	f = 1 MHz, unmeasured pins at 0 V		15	pF

[†] All typical values are at $T_A = 25 \,^{\circ}C$ and nominal voltage.

4.4 TIMING CHARACTERISTICS AND REQUIREMENTS

Timing characteristics and requirements are given in Section 4.4.1 through Section 4.4.6; relevant timing diagrams are shown in Figure 4-1 through Figure 4-9.

4.4.1 Clock and Host Interface Timing Requirements Over Full Range of Operating Conditions

2000 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 - 100 -	PARAMETER	MIN	TYP	MAX	UNIT

th(CE)	CE hold time	80			ns
t _{su} (GR)	ACCGR setup time	100			ns
th(GR)	ACCGR hold time	80			ns

4.4.2 Host Interface Timing Characteristics Over Full Range of Operating Conditions

	PARAMETER	MIN	TYP	MAX	UNIT
ta(CE)	Access time from CE			150	ns
ta(DBIN)	Access time from DBIN			150	ns
t _{su(AD)}	Address setup time to CE	0			ns
tz(DBIN)	Hi-Z time from DBIN		50	100	ns
tz(CE)	Hi-Z time from CE		50	100	ns
ta(GR)	Access time from ACCGR			150	ns
tz(GR)	Hi-Z time from ACCGR		50	100	ns
td(GR/RQ)	Delay of ACCRQ high from ACCGR			100	ns

4.4.3 Source Handshake Timing Characteristics Over Full Range of Operating Conditions (see Note 1)

	PARAMETER	TEST CONDITIONS	MIN	MAX	UNIT
	Delay of DAV true from end	Normal T ₁ (see Note 2)	12(ø)†	$12(\phi)$ + 310	ns
td1	of write operation to	Short T ₁ (see Note 2)	8(ø)†	8(ø)†+310	ns
	data out register	Very short T ₁ (see Note 2)	4(ø)†	$4(\phi)$ 1 + 310	ns
	Delay of valid GPIB				
td2	data lines from end of			140	ns
	write cycle				
	Delay of BO interrupt	BO interrupt		300	
^t d3	from DAC true	unmasked		300	ns
^t d4	Delay of ACCRO DAC true			300	ns
td5	Delay of DAV false from DAC true			160	ns

NOTES:

1. The timing of the source handshake is the same whether ATN is true or false, i.e., whether the device is in TACS, CACS, or SPAS.

 A very short bus settling time (T₁) occurs on the second and subsequent data byte sent when ATN is false if the 'vstd1' feature is set. A slightly longer bus settling time takes place if 'std1' is set unless there is a very short bus settling time. In all other instances, a normal bus settling time occurs.

4.4.4 Acceptor Handshake Timing Characteristics Over Full Range of Operating Conditions

	PARAMETER	TEST CONDITIONS	MIN	MAX	UNIT
^t d6	Delay of BI interrupt from DAV true	BI interrupt unmarked ATN = false device is in LACS	2(ø)†	2(ø)†+415	ns

SN75160/161/162 DATA SHEETS

Texas Instruments SN75160 family of bus transceivers are designated to provide the interface between the bus and the bus controller. These transceivers may be used with the TI TMS9914 Bus Controller chip or any of the other GPIB controllers commercially available. They provide the simplest method of interfacing to the bus, because each part is tailored to either the 8-line data bus or 8-line control bus, so they require no extra logic or complicated board layout. With the SN75160 family, it takes only two 20-pin DIP packages to get on the GPIB. The new improved SN75160A series is pin-for-pin compatible with the original SN75160 series but with lower power and faster speeds, as shown in Figure C-1.

All transceivers in the SN75160 family have several features in common. Each driver output has built into it the termination network required by IEEE Standard 488. This termination is designed so that when power is removed from the transceiver, the output presents a high impedance to the bus. Also, each receiver has a minimum of 400 mV hysteresis for additional noise margin.

The SN7516OA is designed to implement the 8-line data bus. The direction of data flow is controlled by the Talk Enable (TE) input. All eight channels are simultaneously in the receive mode when the TE is low and data is received fron the bus and transferred to the bus controller. When the TE is in the high state, all eight channels go to the transmit mode, and data will be transmitted onto the bus. Each driver features a totem-pole output which can actively drive the bus high or low to give the fastest data rates possible. The SN7516OA has a Pull-up Enable (PE) input which, when taken low, disables the upper stage of the driver outputs turning all eight driver outputs into open-collector type outputs. The open-collector output mode does not allow as fast a data rate as with the totem-pole, but it does allow more than one instrument to be transmitting on the bus at the same time. This feature is used in parallel polling where up to eight instruments may be polled simultaneously, each responding on one line of the eight-line data bus, greatly speeding the polling process. They may then be switched back to the totem-pole mode for regular data transmission.

The SN75161A is used to implement the 8-line control bus. Included in it is the necessary logic which, combined with the Talk-Enable (TE) and Direction Control (DC) inputs, insures that each channel is enabled in the correct direction for exchange of bus management and handshaking signals. Three of the channels, NDAC, NRFD, and SRQ, have open-collector driver outputs as required by the IEEE Standard 488. These lines are always used in a wired-OR configuration. The other five channels have totem-pole outputs. The SN75162A offers an alternate method of implementing the control bus. The SN75162A is identical to the SN75161A except that the direction of the REN and IFC channels is controlled by a separate input called the System Controller (SC). With this additional flexibility, control of the entire Bus System may be transferred from one instrument to another (multiple controller systems). Because of this extra input, the SN75162A package has 22 pins.

SN75160A, SN75161A AND SN75162A OCTAL IEEE-488 GPIB BUS TRANSCEIVERS

features

- 8-channel bidirectional transceivers
- Meet IEEE standard 488 1978
- Low power dissipation (65 mW max per channel)
- High-impedance PNP inputs
- Receiver hysteresis (500 mV typ)
- Open-collector driver output option (SN75160A)
- Bus-terminating resistors provided on driver outputs
- No loading of bus when device is powered down (V_{CC} = 0 V)
- SN75161A for single-controller systems; SN75162A for multi-controller systems

NOTE: Integrated Schottky-Barrier diode-clamped transistor is patented by Texas Instruments. U.S. Patent Number 3,463,975.

description

These octal bus transceivers are designed to provide communication on the general-purpose interface bus (GPIB) between operating units of the instrumentation system. The sixteen signal lines are normally required by the SN75162A in systems with more than one controller. An active turn-off feature has been incorporated into the busterminating resistors so that the devices exhibit a high impedance to the bus when $V_{CC} = 0 V$.

When PE is low, the bus outputs of the SN75160A have the characteristics of open-collector outputs. They act as three-state ports when PE is high. Taking TE low places those ports in the free-state, wherein they can be driven by the bus lines, and enables the D outputs.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V _{CC} (see Note 1)	7 V
Input voltage	5 .5 V
Low-level driver output current	100 mA
Continuous total dissipation at (or below) 25 °C free-air temperature (see Note 2)	1150 mW
Operating free-air temperature range	0°C to 70°C
Storage temperature range	- 65 °C to 150 °C
Lead temperature 1/16 inch (1.6 mm) from case for 10 seconds	260°C

NOTES: 1. All voltage values are with respect to network ground terminal.

2. For operation above 25 °C free-air temperature, derate linearly at the rate of 9.3 mW/ C to 740 mW at 70 °C.

table of abbreviations

 $F = free state^*$, H = high level, L = low level, X = irrelevant, Z = high-impedance state.

*This is the high-impedance state of a normal 3-state output modified by the internal resistors to V_{CC} and ground.

modified by the internal resistors to $\mathsf{V}_{\textbf{CC}}$ and ground.

H = high level, L = low level, R = receive, T = transmit, X = irrelevant

[†] ATN is a normal transceiver channel that functions additionally as an internal direction control or talk enable for EOI whenever the TE and DC inputs are in the same state. When TE and DC are in opposite states, the ATN channel functions as an independent transceiver only.

[‡] Direction of data transmission is from the terminal side to the bus side, and the direction of data receiving is from the bus side to the terminal side. Data transfer is noninverting in both directions.

APPENDIX D

EXAMPLE SOFTWARE

DESIGN EXAMPLE

DESIGN OBJECTIVES

- Illustrate the procedures and protocol of the remote and local messages used to configure a controller.
- Illustrate the procedures used to configure a remote instrument to acquire data and then transmit the data over the GPIB bus to some other device.
- Demonstrate the use of the TMS9914 as a controller, talker, and listener.
- Show the software necessary to drive the TMS9914 when it is interfaced to TM990 products.
- Show the elements of hardware design which must be dealt with when interfacing the TMS9914 to an MPU.
- Show the hardware necessary to interface the TMS9914 to the GPIB bus.

STATEMENT OF THE EXAMPLE DESIGN PROBLEM

- TM990/101-based system
- Use the TMS9914 to communicate with the GPIB.
- Configure an HP3455A digital voltmeter to take two-wire resistance measurements.
- Trigger the meter to take a measurement and send the data over the GPIB to the TM990 system.
- Decode the ASCII data into speech and provide a vocal annunciation of the resistance measurement.

SYSTEM COMPONENTS CHOSEN

- Hewlett Packard model 3438A digital voltmeter
 - IEEE-488 compatible device
 - Range and function selection locally selected and indicated in measurement data
 - Remote measurement trigger capability
- TI TM990/101M microcomputer CPU module
 - TMS9900 16-bit CPU
 - 4K bytes of RAM mappable to either the bottom or top of the memory address space
 - Up to 8K bytes of EPROM at the bottom of memory space
 - TMS9901 programmable system interface providing up to 16 prioritized maskable interrupts and interval timer
 - Two serial I/O ports (RS232C compatible)
 - TI TM990/306 speech module
 - TM990 series bus compatible
 - 180-word vocabulary
 - 2.5 W amplifier for direct speaker drive
 - Programmed through TMS9900 CRU interface
 - Serviced on interrupt or polled basis
 - Additional edge connector for interfacing to non-TM990 devices
- TI TMS9914-based interface board
 - Designed to illustrate the interfacing of the TMS9914 to a CPU and to the IEEE-488 bus
 - Interfaces directly to the components described above

FIGURE D-1 – APPLICATIONS HARDWARE BLOCK DIAGRAM

PROGRAMMER'S MODEL OF THE TM990/306 SPEECH BOARD

- 14-bit address selects word to speak - Bits 16 to 29 on the CRU interface
- 1 bit to enable EPROM speech data
 Set to 1 during initialization
- 1 bit to start/stop speaking
 0 starts/enables speech
 1 stops/disables speech
- 1 bit to indicate the busy status of speech board
 0 means speech board busy
 1 means speech board not busy

METER DATA OUTPUT CHARACTERISTICS

- Data is output as a string of ASCII characters.
 Format of the string is +D.DDDE+D,R OD)A
- R indicates the range setting of the meter.
 - '1' = DC volts
 - '2' = AC volts
 - '3' = DC amps'4' = AC amps
 - '4' = AC and '5' = ohms
- EOI message is sent with LINE FEED character.

FIGURE D-2 - TYPICAL SPEECH BOARD USE

FIGURE D-3 - TYPICAL SOFTWARE TO CONTROL DIGITAL VOLTMETER
